Program Structures & Algorithms

Fall 2020

Assignment 2

Task

Complete the benchmarking & insertion sorting code. Further, draw conclusions from analyzing time complexity for the insertion sort.

Evidence

Running time (in milliseconds) of insertion sort for different types & sizes of array:

SIZE N	RANDOM T1	ORDERED T2	REVERSE ORDERED T3	PARTIALLY ORDERED T4
1000	1.589	0.008	2.018	0.766
2000	3.945	0.017	8.081	3.020
4000	16.069	0.033	34.046	12.344
8000	68.687	0.050	127.241	48.029
16000	257.170	0.094	526.254	191.821

It is evident that reverse ordered array displays the poor performance of insertion sort, hence the worst case. Ordered array provides the best case for insertion sort here.

The worst case of insertion sort has time complexity of $O(N^2)$, which can be proven by data analysis using log-log plot

N	LOG(N)	LOG(T3)
1000	9.965	1.013
2000	10.965	3.014
4000	11.965	5.089
8000	12.965	6.991
16000	13.965	9.036

Computing the slopes:

1. Between 2000 & 1000, $(10.965 - 9.965) / (3.014 - 1.013) = 2.001$
2. Between 4000 & 2000, $(11.965 - 10.965) / (5.089 - 3.014) = 2.074$
3. Between 8000 & 4000, $(12.965 - 11.965) / (6.991 - 5.089) = 1.902$
4. Between 16000 & 8000, $(13.965 - 12.965) / (9.036 - 5.089) = 2.045$

Average of slope = 2.001, which seems to converge to 2 and proves that worst case complexity is of order 2 i.e. $O(N^2)$

Conclusion

Time complexities best, average and worst case for insertion are $O(N)$, $O(N^2)$ and $O(N^2)$ respectively.
